# THE PREDICTING OF THE AVERAGE TEMPERATURES EVOLUTION FROM ROMANIA AND THE RESULTS VISUALISATION WITH THE AID OF THE GEOGRAPHICAL INFORMATION SYSTEMS 

Codrut-George BENEDIC, PhD. Stud., Technical University of Civil Engineering Bucharest, codrutbenedic @ gmail.com<br>Iohan NEUNER, Prof. PhD. Eng, Technical University of Civil Engineering Bucharest, hneuner@gmail.com

#### Abstract

In this article we have tried to present some significant aspects regarding the evolution of average temperatures in Romania. For the study, the statistical data provided by the National Meteorological Administration were used. Finally, it was presented the way of temperatures evolution, through suggestive maps, made using GIS applications.

Keywords: predicting, temperatures, visualisation, maps, GIS

## 1. Introduction

The purpose of this article is to study whether from the evolution of the yearly average temperatures recorded in our country can be deduced a certain cyclicity or can establish an upward / downward trend, leading to as realistic as possible prediction for a reasonable period of time.

The estimation of meteorological phenomena began in the ancient times. According with [2], for this thing the periodic astronomical and meteorological events were taken into account, in order to monitor the seasonal changes of the weather.

Around 650 B.C., the Babylonians tried to estimate the short-term weather changes determined by the appearance of the clouds.

According to [1], at the beginning of the 19th century, the greatest progress was made in weather forecasts, such as understanding how the winds rotated clockwise around a low pressure point.

Another innovation of this century is that represented by the weather charts. These allowed the visualization of the air masses movement.

With the advent of the electric telegraph, real-time meteorological data could be collected.

The leap in terms of weather forecasts is represented by the emergence of the satellite technologies. The first meteorological satellite, named "Vanguard 2", was launched on February 17, 1969, by the United States, as stated in [6].

According to [5], the images provided by the satellites are used as input data in weather forecast models. Thus, when the accuracy of the input data it is better, the variables of a model can be determined more precisely.

Also, the GPS systems on the commercial aircraft provide data retalating to the wind speed and the temperatures at the aircraft flight altitudes, helping to make more accurate weather forecasts, as shown in [4].

## 2. The location of the weather stations used in this study

In this article we used the data obtained from the National Meteorological Administration, from 24 weather stations, regarding to the evolution of the monthly average temperatures.

The data used within the study are significant and we consider that these are quite conclusive, because these cover half a century, from 1961 to 2013.

The location of the weather stations taken into consideration in the study concerning to the evolution of the yearly average temperatures in Romania, it is presented in figure 1.

Figure 1. The location of the weather stations used in study
In figure 1, the weather stations represented with yellow there are those for which we obtained data regarding to the evolution of the monthly average temperatures from 1961 to 2013, from the National Meteorological Administration.

## 3. The analysis of the yearly average temperatures evolution

Starting from the monthly average temperatures, we calculated the yearly average temperatures from 1961 to 2013. The values thus obtained were transposed in the graph with their evolution, presented below.

For the ease of the evolution visualising of the yearly average temperatures, we averaged the values of the temperatures from each year, from all the weather stations used in the study and we represented the results within the graph in figure 2.

Figure 2. The evolution of the yearly average temperatures from 1961 to 2013
From the graph shown in figure 2 it can be seen the variation of the yearly average temperatures from one year to another, with increases and decreases in their evolution. At the same time, it can be seen the increasing trend of the evolution of the yearly average temperatures, represented by the dotted line, shown with red within the figure.

## 4. The method used for the predicting of the yearly average temperatures

To estimate the yearly average temperatures, we adapted the method presented in [3], in order to obtain the variation of the trend values. In the following we explained the forecasting method used, based on the data in figure 3.

In the "B" column, we passed the years, starting from 1961, until 2013, years for which we calculated the values of the yearly average temperatures based on the data regarding the evolution of the monthly average temperatures. Then we passed the years, starting from 2014, until 2050, for which we estimated the values of the yearly average temperatures.

We passed in the "C" column the calculated and estimated yearly average temperatures.
To calculate the values presented within the table in figure 3, we used the mathematical relationships presented below.

$$
\begin{equation*}
\overline{\mathrm{T}_{\mathrm{y}}^{\mathrm{i}}}=\frac{\sum \overline{\mathrm{T}_{\mathrm{m}}{ }^{\mathrm{i}}}}{\overline{12}} \tag{1}
\end{equation*}
$$

where: $\overline{T_{y}{ }^{i}}$ represents the yearly average temperature corresponding to the " i " year;
$\overline{\mathrm{T}_{\mathrm{m}}{ }^{i}}$ represents the monthly average temperatures in the "i" year.

$$
\begin{equation*}
\mathrm{M}_{\mathrm{i}+1}=\frac{\overline{\mathrm{T}_{\mathrm{y}}{ }^{\mathrm{i}}}+\overline{\mathrm{T}_{\mathrm{y}}{ }^{\mathrm{i}+1}}}{2} \tag{2}
\end{equation*}
$$

where $M_{i+1}$ represents the successive averages of the yearly average temperatures, values shown in the "E" column of the table in figure 3.

$$
\begin{equation*}
\mathrm{I}_{\mathrm{v}}{ }^{i+1}=\frac{\mathrm{M}_{\mathrm{i}+1}}{\overline{\mathrm{M}_{\mathrm{i}+1}}} \tag{3}
\end{equation*}
$$

where $\mathrm{I}_{\mathrm{v}}{ }^{i+1}$ represents the variability index, expressed as a percentage, calculated within the column " F ", as the ratio between the value of the successive average in the " $\mathrm{i}+1$ " year and the arithmetic mean of the values of all the successive averages in the " $E$ " column.

$$
\begin{equation*}
\mathrm{V}_{\mathrm{u}}{ }^{\mathrm{i}+1}=\frac{\overline{\mathrm{T}_{\mathrm{y}}{ }^{\mathrm{i}+1}}}{\mathrm{I}_{\mathrm{v}}{ }^{i+1}} \tag{4}
\end{equation*}
$$

where $V_{u}{ }^{i+1}$ represents the underlying value, calculated as the ratio betweeen the yearly average temperature in the " $i+1$ " year and the value of the variability index from the same year.

For the first year, the underlying value has been calculated using the following mathematical relationship:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{u}}{ }^{1961}=\frac{\overline{\mathrm{T}_{\mathrm{y}}{ }^{1961}}}{\mathrm{I}_{\mathrm{v}}{ }^{2012}} \tag{5}
\end{equation*}
$$

For the next years, the underlying values have been determinated by applying the (4) relation.

$$
\begin{equation*}
V_{e}=\overline{V_{u}{ }^{\mathrm{i}}}-\frac{\sum(\mathrm{i}-\overline{\mathrm{i}}) \cdot\left(\mathrm{V}_{\mathrm{u}}{ }^{\mathrm{i}}-\overline{\mathrm{V}_{\mathrm{u}} \mathrm{i}}\right)}{\sum(\mathrm{i}-\overline{\mathrm{i}})^{2}} \cdot \overline{\mathrm{i}}+\frac{\sum(\mathrm{i}-\overline{\mathrm{i}}) \cdot\left(\mathrm{V}_{\mathrm{u}}{ }^{\mathrm{i}}-\overline{\mathrm{V}_{\mathrm{u}}{ }^{\mathrm{i}}}\right)}{\sum(\mathrm{i}-\overline{\mathrm{i}})^{2}} \cdot \mathrm{i} \tag{6}
\end{equation*}
$$

where: $\mathrm{V}_{\mathrm{e}}$ represents the estimated values of the the underlying values, calculated in the " H " column of the table;
i represents the number of the year, from 1961 to 2013, inclusive;
$\bar{i}$ represents the average value of the number of the year;
$V_{u}{ }^{i}$ represents the underlying value in „i" year;
$\overline{V_{u}{ }^{i}}$ represents the average of the underlying values, previously calculated.

$$
\begin{equation*}
\overline{\mathrm{T}}_{\mathrm{e}}=\mathrm{V}_{\mathrm{e}} \cdot \mathrm{I}_{\mathrm{v}}{ }^{\mathrm{i}+1} \tag{7}
\end{equation*}
$$

where: $\overline{\mathrm{T}}_{\mathrm{e}}$ represents the estimated values of the yearly average temperatures, calculated in the "I" column and passed in the "C" column of the table, from 2014 to 2050;
$\mathrm{I}_{\mathrm{v}}{ }^{\mathrm{i}+1}$ represents the values of the variability index. In this case, " i " takes values from 1973 to 2009, depending on the year for which the yearly average temperature is estimated.

To exemplify the calculation method used, we took into account the yearly average temperatures recorded at the weather station from Arad.

Figure 3. The determination of the predicted values for the yearly average temperatures

## 5. The evolution mode visualisation of the yearly average temperatures from the 1961 to 2050

In order to see the evolution of the yearly average temperatures from 1961 to 2050, we made maps every 10 years, in which the yearly average temperatures were classified into 5 classes, from $6^{\circ} \mathrm{C}$ to $14^{\circ} \mathrm{C}$, every 2 degrees.

To make the maps we used the "QGis" application, 2.14 .14 version, and we interpolated the values of the yearly average temperatures by the method of the inverse distance weighting.

Figure 4. The yearly average temperatures in 1961

Figure 6. The yearly average

Figure 8. The yearly average

Figure 5. The yearly average temperatures in 1970

Figure 7. The yearly average temperatures in 1990

Figure 9. The yearly average

Figure 10. The yearly average temperatures in 2020

Figure 12 . The yearly average temperatures in 2040

Figure 11. The yearly average temperatures in 2030

Figure 13. The yearly average temperatures in 2050

From the analysis of the resulting figures it can be seen that from 1961 to 1990 the yearly average temperatures are on a downward slope, and from 1990 to 2050, these register increases throughout the country.

## 6. Conclusions

The Romania's specific climate is a temperate continental one, in which the monthly average temperatures vary between $22^{\circ} \mathrm{C}$ and $24^{\circ} \mathrm{C}$ during the summer, respectively between $-3^{\circ} \mathrm{C}$ and $-5^{\circ} \mathrm{C}$ during the winter.

The method used to predict the values of yearly average temperatures has the disadvantage that when we have positive and negative values, "aberrant" values may result from the forecast. Therefore, this method is not good for predicting monthly average temperature values.

This is due to the fact that incorrect values of the variability index result from the calculation of successive averages.

Instead, for the polar or equatorial areas, where the monthly average temperatures record only negative or positive values, the method will give good results for the monthly predictions, too.

From the evolution of the yearly average temperatures, there is a tendency to increase them on average, by $2^{\circ} \mathrm{C}$, throughout the country, from 1990 to 2050 .

This could be due to the industrial development, the increase of the cars number, the old technologies used before 1990, which have become very polluting, as well as the uncontrolled deforestation.
